Method of and device for dispensing viscous concentrates of variable viscosity in 5 accurately metered quantities of variable voluma

This invention relates to a method of and a device for dispensing viscous concentries of 10 variable viscosity in accurately metered quantities of variable volume in which cyclic variations of the pumping volume of a hollow body made of a flexible or elastically deformable material cause said concentrate to be drawn in 15 from the storage volume of a container via a non-return valve and to be discharged on the output side via a second non-return valve.

There have been known a variety of metering pumps in the form of discharging sections 20 provided with two non-return valves, one of which functions as an inlet valve, the other one functioning as an outlet valve. For example, there has been disclosed in British Patent Specification No. 827 778 a metering pump 25 in which the discharge section is formed by a flexible tube which is adapted to be closed by the application of a radial squeezing pressure by means of an actuating device and which tends again to assume its full open cross-30 section upon said actuating device being released. Opening of the inlet valve or the outlet valve, respectively, is effected by pressure changes caused in said discharge portion. Such a device is not only hard to manipulate 35 properly but permits only a relatively inaccurate metering effect to be obtained. Therefore, such devices may be considered suitable for use with soap dispensers and the like in which metering accuracy is not at a premium. 40 Besides, the means serving to operate said discharge section are extremely complicated

It has further been known to provide a discharging section with a radially outwardly 45 projecting bellows-like fold which is adapted to be compressed in an axial direction between a pair of plate-shaped actuating elements so as to serve the function of a metering pump. In this case it is also possible to 50 construct the discharging section as a rubber bellows which has associated therewith suitable beak-like rubber valves forming non-return valves (cf. United States Patent Specification No. 25 54 570). This known device also 55 occupies considerable space and is, therefore. not suitable for installation in vending machin s or the like. The metering volume of this known device is als relativ ly inaccurate so that it is xtremely difficult to insure 60 accurate metering.

and expensive.

Where it is desired to dispense metered quantities of certain highly viscous concentrates, an extremely accurate metering operation is necessary. In view of the fact that in 65 certain applications, such as beverage vending machines, extremely little space is available for m chanicl quipment, it is n cessary to provide a metering device which is of as compact design as possible. A particularly

70 serious problem arises from the fact that concentrates of perishable organic substances pose great difficulties as regards the maintenance of hygienic conditions, particularly in cases in which the metering device and/or

75 accessories thereof may be contaminated by drops of such substances. If all hygienic requirements are to be met, the necessary maintenance operations and frequent cleaning of component parts prove to be extremely diffi-

80 cult and time-consuming, it being necessary to provide for constant supervision of such operations,

In the prior-art metering devices comprising a peristaltic pump or a similar tube-shaped 85 discharging section, only a relatively small restoring force is produced upon the elastic tube material being subjectd to small amounts of deformation. The restoring force is not increased sufficiently unless a major amount

90 of deformation is caused. However, the magnitude of the restoring force also affects the accurate reproduceability of the deformation and thus the accuracy of the metering operation. Therefore, these known devices are only

95 adapted to dispense relatively large volumes of the concentrate, and the frequency with which metering cycles can be performed is relatively low. The term "relatively large volumes" is understood to mean, for example,

100 volumetric quantities of 0.4 cubic centimeters. Nor is it possible to prestress or bias a filled flexible tube section in its initial position because it is necessary to thread the tube sections into an actuating device such as a peris-

105 taltic pump, it being necessary to avoid any deformation in order to prevent any drops of liquid.

Another important factor tending to impair the metering accuracy of such known devices 110 resides in the fact that, during a decrease in the pumping volume, the tube-shaped discharging section is subjected to uncontrollable additional deformation caused by the increased pressure occuring within said section. Such

115 uncontrollable variations may only be tolerated where a relatively large metering volume is discharged during each cycle so that the influence of such variations remains small.

In view of the foregoing, it is an object of 120 this invention to improve the method described above as well as the device for practicing said method in such a way as to avoid the disadvantages thereof and to enable ven extr mely small quantities of a concentrate to be

125 dispensed in an extremely accurate manner and at a high cycling frequency. It is a further object of this invention to provide a device for practicing the method which is of xtremely compact construction so as to permit it to be

130 easily accommodated in a small space, for

example, in a beverage vending machine, or to permit the device to be installed in existing vending machines.

This object is attained by the provision of the method having the features defined in claim 1, the method of the invention being capable of being practiced by means of a device having the features defined in claim 4.

According to the inventiion, a pumping ef-10 fect is produced by decreasing in an axial direction a cylindrical pumping volume which is supported in a shape-maintaining manner during the volume reducing operation with the result that uncontrollable deformation due to 15 the increasing pumping pressure and changes in the metering volume are avoided. In this manner it is possible to provide an extremely high degree of precision of the metering operation even in cases in which extremely small 20 quantities are dispensed per metering cycle. The axial compression of the cylindrical metering volume makes it possible for the hollow cylindrical body defining the pumping volume to be subjected in its initial position to a 25 presettable axial bias in the sense of a increase in said volume. This results in the provision of sufficiently large restoring forces even with changes in volume of minimum magnitude. Moreover, this axial compression 30 of the pumping volume in conjunction with the extremely high accuracy capable of attainment even with extremely small metering volumes makes it possible to provide a frequency of metering cycles which is in agreement with 35 the power mains frequency, i.e. a frequency of 50 to 60 Hz. This high cycling frequency

45 controlled devices.
Despite the bias which exists in the inoperative position of the pumping volume, the discharging section can be easily and reliably threaded into the actuating means without
50 drops of liquid being dispensed in an undesired manner. At the same time the hygienic problems are completely avoided which might otherwise be caused by contamination of the device. In addition, the arrangement just described is improved considerably by the fact that all components which are of importance as regards reliable functioning of the device are enclosed in a rigid guiding tube which is

and the smallness of the quantities capable of

total quantity to be discharged to be selected

being metered make it possible to vary the

suitably controlling the number of metering

pulses per unit time. This method of control

can be implemented in an extremely simple

and reliable manner with mains-frequency

40 within a large range of adjustment simply by

either permanently or releasably connected to 80 a container for shipping, storage and dispensing of the liquid, said container preferably being a single-use product.

The high cycling frequincy of the device tus permits the liquid to be dispensed in the 65 firm of an almost continuous flow or stream

with the ald of a train of rapidly repeated m tering cycles with the length of said train being capable of being adjusted to suit requirements.

70 The sleeve-shaped body of the device need only be of flexible nature, it being possible, by the addition of suitable elements such as spring elements or the like, to provide for the necessary bias and restoring action. In a pre-

75 ferred embodiment, however, the sleeve body is made of a shape-retaining elastic material and secured to rigid hub-shaped bodies of said non-return valves.

The small dimensions of the dispensing 80 section makes it possible to install the device in a vending machine in which extremely little space is available. An additional adventage of the device of the invention makes it possible to modify existing metering devices by the

85 addition of an electromagnectic annular coil for the purpose of substituting a quantity controlled or volume controlled metering method for the time controlled metering method described where time controlled met-

90 ering would result in undesirable fluctuations of accuracy due to changes in the viscosity of the liquid. The metering accuracy of the device of the invention is not affected by such variations in consistency.

95 The invention and further particulars will be described more specifically hereinafter with reference to a preferred embodiment shown in the drawings, in which:—

Figure 1 is an axial cross-sectional view of a 100 container for the storage, transportation and dispensing of a liquid, the container being provided with a dispensing section according to the invention;

Figure 2 is an enlarged exploded cross-105 sectional view of the component parts of the dispensing section; and

Figure 3 is an enlarged cross-sectional view of a modified embodiment of the dispensing section.

10 Preferably the device of the invention is manufactured in the form of a single-use container which is adapted to store, transport and dispense metered quantities of a liquid. Preferably, the dispensing section is perma-

115 nently secured to the container during manufacture thereof and is discarded together with the container after use. Thus, the container constitutes a mass-produced item.

Said container may comprise an external 120 envelope and an interior flexible bag adapted to contain the liquid and to collapse as liquid is being withdrawn. With this construction, it is not necessary to introduce air into the container to permit liquid to be dispens d.

125 However, it w uld also b possibl to provide an essentially rigid container with which ventilating m ans are ass clated which are adapted to be actuated for the purpose of dispensing liquid.

130 It should be understood that the container

is preferably intended for the reception, storage and transportation as well as the disp na-

ing of organic concentrates. In the embodiment shown in Fig. 1 the 5 container comprises an external envelope 1 and a flexible and collapsible liquid-receiving container 2 which latter is provided with a mouthpiece 3 to which the dispensing section 4 is preferably permanently attached. In Fig. 10 1 the container is shown in the inverted position in which it is held when it is intended to dispense metered quantities of a liquid. In this position, the dispensing section 6 extends through the central aperture of an electromag-15 nectic annular coil 5 which may, for example, be fixedly installed in an automatic beverage vending machine. The electromagnetic annular coll 5 is connected to suitable control means which make it possible, for example, to 20 operate the electromagnetic annular coil 5 at the power mains frequency with the number of oscillations coil 5 is desired to follow being

adjusted with the aid of said control means. Dispensing section 4 comprises a rigid tu-25 bular guide member 6 made of a plastic material, the upper end of which is Permanently secured to mouthpiece 3 of the container. As shown in Fig. 2, tubular guide member 6 is provided with a free cross sec-30 tion through a major part of its length forming an enlarged portion extending downwardly from an annular shoulder 35. The tubular guide member 6 has associate therewith a rigid cover member 26 at its lower end, this 35 cover member being provided with a central discharge spigot 27. In the embodiment shown the two members 6 and 26 of the tubular guide member are interconnected by a hub-shaped valve body 20 which is provided 40 with an external annular flange 22 serving as an abutment up to which the tubular guide member and the cover member 26 may be slid over the valve body so as to hold the members in position. In this arrangement, the 45 hub-shaped valve body 20 is rigidly connected to both the tubular guide member 6

and the cover member 26. Another similar hub-shaped valve body 8 is received with clearance by the larger-diameter 50 portion of guide member 6 so as to be capable of freely moving in an axial direction within guide member 6. A spigot-shaped terminal portion of valve body 8 made of a plastic material facing container 1 in an up-55 ward direction has attached thereto a magnetizable sleeve member 7 forming an annular armature, the lower annular should r f said member bearing against shoulder 9 of valv b dv 8. Thus, valve body 8 and annular 60 armature 7 constitute a rigid unit which is axially movable upwardly and downwardly within guide member 6 as indicated by the double-headed arrow 31.

The mutually facing ends of valve bodies 8 65 and 20 are provided with receiving and

mounting p rtions 10, 11 and 19, 21, r - spectively, for the sleeve-shaped end portions 16 and 18 of a hollow cylindrical body 15. In the embodiment shown, body 15 is made of

70 an elastic material so that it also serves the function of an elastic spring element. As shown in Fig. 2, body is 15 provided with termina! portions 16 and 18 of greater wall thickness serving to mount the two valve

75 bodies 8 and 20 and is also provided with a radially inwardly projecting fold or bead 17 of smaller thickness. Body 15 connecting the hub-shaped valve bodies 8 and 20 defines a predetermined metering volume between the 80 valve bodies. The initial capacity of this vol-

80 valve bodies. The initial capacity of this volume is determined by the restoring action of body 15 in conjunction with the internal shoulder 35 of tubular guide member 6 on which the annular upper end face of annular 85 armature 7 bears in the rest position.

In the embodiment shown, each of the valve bodies 8 and 20 is provided with a central bore 12 and 24, respectively, into which there may be spring-fitted a shaft por-

90 tion of a valve element 14 or 25, respectively, said valve elements being of mushroom shape and made of an eleastic material. A tapered enlargement provided on the free end of each mushroom-shaped portion serves to lock the

95 viave element to its associated hub-shaped valve body. The lip-shaped peripheral edge of the dish-shaped head portion of valve element 14 or valve element 25, respectively, is caused by the variable pressure to which it is

100 subjected to bear seatingly against the adjacent inner end face of the respective hubshaped valve body 8 or 20. The inner portions of said valve bodies are provided with a plurality of passages 13 and 23, respectively

105 each plurality forming a circular arrangement, said passages permitting liquid to enter the metering space and to be discharged therefrom, respectively. Under static conditions, the elastic blas produced by the material of

110 the mushroom-shaped valve elements 14 and 25 is sufficient to prevent liquid from flowing through passages 13 and 23. Only with pressure variations exceeding such static conditions will the lip-shaped peripheral edges of

115 the dish-shaped head portions of the valve elements be lifted off the central end faces of said hub-shaped valve bodies 8 and 20 so as to permit liquid to flow through said passages.

The stroke length of the assembly formed 120 by valve body 8 and annular armature 7 in an upward direction is limited by the internal shoulder 35 f tubular guid member 6. In a downward direction the strok length f said assembly is limit d by the fact that during

125 such downward motion the lower edges of portion 10 of the hub-shaped valve body 8 comes int contact with the annular upper edge of portion 21 of hub-shaped valve body 20. Without the design f this arrangem nt

130 being changed, it is possible by suitably se-

lecting the length of porti as 10 and 21 easily and accurately t adjust the stroke length 30 (Fig. 1) of th movabl assembly 7, 8. As valve body 8 approaches valve body 5 20, portions 10 and 21 thereof enclose the hollow cylindrical body and support it from the outside in such a manner that it cannot change its shape, the result being that body 15 cannot be expanded in a radial direction.

10 Figure 1 shows the component parts of the embodiment just described approximately in their actual size, the stroke length of this preferred embodiment being a little smaller than shown at 30 in Fig. 1. The liquid volume 15 dispensed through spigot 27 is determined by the number of pumping strokes occurring at the power mains frequency. Therefore, this volume can be easily adjusted because the Individual quantities discharged during each 20 pumping stroke can be adjusted in an extremely accurate manner even in the case of very small increments. Within the dispensing section 4 the liquid is hermetically sealed so as to be protected against the action of at-25 mosheric oxygen. It is seen that the arrangement described is capable of being manufactured in a simple manner and at low cost, that it operates in a very reliable manner, that its manipulation is extremely simple and safe, 30 and that no contamination of components located in the vicinity of the device is

The stroke length may also be limited by means of stop members of different construc-35 tion which are provided, for example, on the tubular guide member.

possible.

In order to avoid radial deformation of the hollow cylindrical body in the vicinity of the radially inwardly projecting bead 17, it may 40 be of advantage to provide the or each bead in the area of its internally projecting ridge with a rigid supporting ring.

More specifically, it may be of particular advantage to give the ridge of the bead a 45 helical shape. In this case it is possible to provide in association with said ridge a supporting element in the form of a helically extending spring element which is adapted to be compressed in an axial direction only, said spring element serving the additional function of axially blassing the hollow cylindrical body 15. In the latter case body 15 need not be of a shape-elastic nature if it is made of a material having a sufficient degree of flexibility.

Under certain conditions it is possible to dispense with the non-return valve 25 provided on the discharge end of the divice.

In this case the non-return valve at the exit 60 of the pumping volume is replaced by a discharge spigot which is in un betructed connexion with the pumping space. The inner diamter and the length of such a discharge spigot are so selected that the inner friction 65 and the surface tension of the concentrate

present in the discharge spigot suffic to retain the concentrat column in its axial position within the discharge spigot with the pumping volume remaining unchaged or be70 ing increased. The pumping volume will re-

main constant as long as the non-return valve at the entering end of the device is closed. With the pumping volume being increased, concentrate will be withdrawn from the con-

75 tainer and transferred into the pumping space. In a practical embodiment of this modified device of the invention, the inner diameter of the pumping space amounted to between 8 and 12 mm. The stroke length was adapted

80 to be adjusted between 1 and 2 mm. The stroking frequency amounted to 50 cycles per second, but it was possible to vary this frequency between 10 and 100 cycles per second without the operation of the device being

85 impaired. The device was tested with liquids having a viscosity ranging from 1 to 100 centipoise units. The non-return valve located on the entry side was provided as passages with slots arranged on a semicircle and

90 adapted to be covered by a small valve plate. It was found that no dripping of concentrate had to be expected with a length between 10 and 40 mm of the discharge spigot replacing the exit valve with an inner diameter of said

95 spigot between 1 and 3 mm.
Without the flexible body or bellows 15

being supported by the corset-like arrangement, said bellows will be subject to an irregular formation of externally curved por100 tions, this phenomenon impairing the accuracy of the metering operation. In contrast to this, the corset-like supporting means of the invention makes it possible to maintain volumetric tolerances of hardly measurable magnitude.

Figure 3 shows a modified embodiment of the component parts defining the pumping space. Mounted in a cylindrical housing 40, the upper end of which is adapted to be

110 connected to the container for the concentrate, is an upper sleeve member 42 which is provided with an outwardly projecting flange at its upper end. A corresponding lower sleeve member 43 is provided in the lower end of

115 housing 40 and rigidly attached to a cover member having an outlet spigot 49. In the example shown, it is assumed that the lower sleeve member 43 is guided with clearance in the lower end of housing 40. Also the lower

120 sleeve member 43 is provided with an outwardly projecting flange. Between the lower portion of housing 40 and the two approximately aligned spigot sections 42 and 43 which are made of a rigid material such as a

125 plastic mat rial there is provided an annular space 47. Disposed in this annular space is a spreading r blasing spring 48 the ends of which bear against the flanges of sleev members 42 and 43, said spring tending to hold

130 the two sleeve m mb rs in th ir spread-apart

15

position shown in Fig. 3. In the embodim nt shown the lower spigot is connected to an annular armature 45 which is adapted to be actuated in such a manner by the electromag-5 netic operating means (not shown) that the lower spigot 43 can be raised until it bears against the upper spigot 22 for the performance of a pumping stroke. The two opposing ends of the two spigots are sealingly 10 interconnected by a bellows member 44 which essentially applies no forces to the spigots. With the two spigots 42 and 43 being brought into their proximate position, the fold 44 is practically closed completely.

In order to prevent air from being compressed in the annular space 47 in synchronism with the pumping strokes, said annular space is ventilated to the external atmosphere via slots or drilled holes 50 which should be 20 arranged at the minimum possible distance from the final position attained during a pumping stroke so as to provide a flow path of minimum length for the air displaced as the volume of annular space 47 is varied. Pro-

25 vided in the vicinity of the upper flange of spigot 42 is the inlet valve (not shown) of the pumping chamber, it being possible to provide an inlet valve which resembles the embodiment described earlier. In Fig. 3 the

30 pumping motion of the lower sleeve member 43 is indicated by the double-headed arrow 46. It would also be possible to provide an arrangement in which the two sleeve members are adapted to move towards and away 35 from one another. The embodiment shown in Fig.3 affords the advantage that no concen-

trate can enter the annular space 47. The spigot 49 can be constructed in such a way that it is not necessary to associate a non-

40 return valve to the outlet.

It will be understood that such an arrangement which is operable independently of the elastic restoring force of a rubber bellows is capable of metering almost paste-like media 45 which are not adapted to be metered by means of the normally available restoring force provided by a shape-retaining elastic body. In this case it will be necessary to provide the magnetic forces in a suitable 50 manner. The spring force can then be deter-

mined in an analogous manner.

The metering device of the invention is also suitable for fluids other than syrups and the like. Particularly in the case of perishable 55 fluids, the pump elements employed in the single-use unit afford the advantage that it is possible by suitable manufacturing methods to limit the useful life, for example f the diaphragm, with the result that illegal refilling 60 of the container will caus rapid d teriorati n of th dlaphragm so as to render the device useless. This is an effective method of preventing hygienic pr bl ms from erising.

1. A method of disp nsing viscous concentrates of variable viscosity in accurately meterable quanties of varying volume in which cyclical chang s of the pumping vol-70 ume of a hollow body made of a flexible or shape-retaining elastic material cause said

concentrate to be withdrawn from the storage space of a container via a non-return valve and to be discharged on the exit side via a

75 second non-return valve, caracterized in that the cylindrical pumping volume is cyclically varied in the direction of its longitudinal axis between stop means and that during each reduction in said volume said hollow cylindri-

80 cal body is supported externally by shaperetaining means against any deformation in a

radially outward direction.

2. The method of claim 1, characterized in that said hollow cylindrical body is elastically 85 biased in an axial direction and in the sense of increasing said pumping volume in its shape corresponding to its larger initial volume.

3. The method of claim 1 or claim 2, characterized in that said cyclical variation of 90 said pumping volume is effected at the frequency of the mains power employed to pro-

vide the pumping action.

4. A device for carrying into practice the method of claim 1 comprising a dispensing 95 section adapted to be operated as a metering pump, said dispensing section being adapted to be connected to the storage space of a container, particularly of a container serving to store, transport and dispense said concen-

100 trate, the dispensing end of said section being connected to a non-return valve adapted to be opened in the dispensing direction, said dispensing section comprising an axially compressible pumping volume and being adapted

105 to be inserted into operating means controlling said pumping volume, characterized in that said pumping volume is provided in a hollow cylindrical body made of a flexible or shape-retaining elastic material, there being

110 associated with said body an actuating element adapted to compress said body in an axial direction, and that there is provided a hollow cylindrical housing which is adapted, at least during the volume reduction phase, to 115 enclose said body from its outside in a shape-

retaining manner.

5. The device of claim 4, characterized in that the rigid valve bodies of the two nonreturn valves are fixedly connected to the 120 ends of said hollow cylindrical body, that said valve bodies are axially moveable relative to one another and that said valve bodies are provid d with wall a ctions which are adapted, when they have approached one

125 another in an axial direction to the largest possible extent, to surround said holl w cylindrical body from the outsid in a shaperetaining manner.

8. The device of claim 4 or claim 5, 130 characterized in that said wall portions of said two non-return valves in addition serve th function of a variable step means adapted to limit the extent to which the non-return valves are permitted to approach one another.

- 7. The device claimed in any of the preceding claims 4 to 6, characterized in that one of said valve bodies is immovably connected to a tubular guide member adapted to receive and enclose said non-return valves, said actu-10 ating member and said hollow cylindrical body, with the other valve body and the actuating element connected thereto, being axially slidably supported in said tubular member.
- 8. The device of claim 7, characterized in that the assembly formed by said valve body and said actuating element, when assuming the position corrresponding to the larger value of said pumping volume, are biased by a
 predetermined biasing force in the direction in which said pumping volume is increased, the bias acting toward an internal stop (internal shoulder) of said tubular guide member.
- 9. The device of claim 8, characterized in 25 that said hollow cylindrical body is made of a shape-retaining elastic material and is clamped in position on an axially compressed condition in its position of rest between said two valve bodies.
- 30 10. A device as claimed in any of the preceding claims 4 to 9, characterized in that said actuating element is constructed as an annular armature and is adapted to be cyclically movable within said tubular guide mem-35 ber together with said valve body by means of an electromagnetic actuating arrangement adapted to be operated at a power mains frequency of between 50 and 60 cycles per second.
- 40 11. A device as claimed in any of the preceding claims 4 to 10, characterized in that there is associated with the movable assembly a spring element adapted to bias said assembly in such a way as to retain it in 45 its initial position.
- 12. A evice as claimed in any of the preceding claims 4 to 11, characterized in that the end portions of enlarged cross section of said hollow cylindrical body made of a 50 shape-retaining elastic material are sealingly mounted on peripheral portions of the hubshaped valve bodies and that said hollow cylindrical body is provided with at least one radially inwardly projecting fold or bead.
- 13. A device as claimed in any of the preceding claims 4 to 12, characterized in that said non-return valves are constructed as mushr om-shaped of m nts made of an elastically deformable material and that said elements are adapted to be each inserted into a central bore of the respective hub-shaped valve body made of plastic material, said el ments functioning in similarity to patent
 - 14. A device as claimed in any of the

fasteners.

85

prec ding claims 4 to 13, characterized in that said tubular guide member comprises a guiding section and an end cover provided with a spigot-shaped discharge portion, said 70 guiding tube and said cover being Interconnected by means of said non-return valve which is mounted in a stationary position on the structure supporting the device.

15. A device as claimed in any of the 75 preceding claims 12 to 14, characterized in that the or each of said internally projecting fold or bead is supported against any radial deformation by a rigid, annular supporting element.

18. The device of claim 15, characterized in that the ridge of the internally projecting bead or fold of said hollow cylindrical body made of a merely flexible or a shape-retaining elastic material is of helical shape and is

85 provided as a supporting element with a yieldable helical spring which is fixedly embedded in said ridge.

17. The device of claim 4, characterized in that said pumping space, instead of being 90 provided on its exit end with a non-return valve, is in free connexion with a dispensing spigot of such internal diameter and such length that the inner friction and the surface tension of said concentrate contained in said 95 dispensing spigot suffice to retain the concert

95 dispensing spigot suffice to retain the concentrate column in an axially unchanged position in said dispensing spigot with said pumping space remaining unchanged (with the non-return valve on the entry side closed) as well

100 as with said pumping space being increased (suction stroke).

18. A device as claimed in any of the preceding claims 4 to 17, characterized in that said pumping space is defined by two

105 rigid hollow spigot elemets and an annular bead or fold made of a flexible material interconnecting the adjacent ends of said spigots, and that there is disposed in the annular space existing between said pumping space

110 and said hollow cylindrical housing a helical spring the ends of which bear against the ends of said spigots facing away from one another.

 The device of claim 18, characterized
 in that ventilating apertures extend between said annular space and the external atmosphere.
